Chapter 10

Team Structure

It is perhaps a myth, but an enduring one, that people and their pets resemble one another. The same has been said of products and the teams that build them.

The system being produced will tend to have a structure that mirrors the structure of the group that is producing it, whether or not this was intended. One should take advantage of this fact and then deliberately design the group structure so as to achieve the desired system structure. (Conway 1968; commonly referred to as “Conway’s Law”)

If it is true that a product reflects the structure of the team that built it, then an important decision for any Scrum project is how to organize those individuals into teams. Factoring into this decision are considerations of team size, familiarity with the domain, the channels of communication, the technical design of the system, individual experience levels, the technologies involved, the newness of those technologies, where team members are located, competitive and market pressures, expectations about project schedule, and much more.

In this chapter we look at the importance of two critical factors to be considered when deciding how to structure Scrum teams: keeping teams small and orienting each team around the delivery of end-to-end user-visible functionality. We also look at the importance of having the right people on each team and not overloading those individuals by forcing them to split time among too many teams. We conclude the chapter with nine questions to ask when starting a multi-team project.

Feed Them Two Pizzas

I was working on a project for a bioinformatics company when the CEO asked me to provide her with an estimate of how long the project would take. The application was large, the domain complicated, and the team mostly new. Because the domain was so complicated, our team was made up of some very smart Ph.D. scientists, who knew only a little about programming, and some very smart
programmers, most of whom had taken no more than a class or two in biology or genetics. No one on the team was great at both the science and the development. After a bit of research and work with the team I returned to the CEO with an estimate of something like 100 person-years. In other words, if we used all 40 people on the team, we could finish the project in about two and a half years. I don’t think that number was too shocking to her, but it was a big number, so she asked me, “What’s the cheapest way we could write it?” My answer: “Take Steve, the scientist with the best understanding and aptitude for programming, and have him go spend 10 years working in a great software company doing nothing but learning how to be a great programmer. Then have him return to our company and spend 30 years working alone to write the program. It’ll take 40 years, but it’s your cheapest option.” She should have been quite pleased with my answer—after all, I’d taken the 100 person-year initial estimate and offered her a way to cut it by more than half. Alas, 40 years was just a bit too long for her to wait.

As this story illustrates, a team offers the advantage of getting things done far more quickly than one person could, but with that advantage comes a potentially large amount of communication overhead. Knowing that, what is the ideal team size for Scrum projects? Generally accepted advice is that the ideal Scrum team size is five to nine individuals. While I agree with this, putting a number to it makes me nervous. If you’re thinking about your ten-person team right now you may feel inclined to return this book, demand a refund, and give up on Scrum. Don’t.

Rather than take the five-to-nine person guideline too literally, I prefer how Amazon.com thinks its about its teams. Amazon refers to them as “two-pizza teams,” meaning a team that can be fed with two pizzas (Deutschman 2007). As humorous as that is, it’s actually useful. If ordering food for the occasional team lunch is a hassle, it could be a good indicator that the team has become too large.

The largest single Scrum team that I worked with where I was content to leave them alone was 14 people. The team, its ScrumMaster, and I had all looked at possible ways to split them up, but no solutions we came up with seemed better than leaving them intact. I’ve also worked with one team of 25 that insisted it should be one team rather than more. They were wrong; there was too much communication overhead on a single team of that size.

**Why Two Pizzas Are Enough**

To be fair, there are some advantages to large teams. Large teams may include members with more diverse skills, experiences, and approaches. Large teams are not as much at risk to the loss of a key person. They may also provide more opportunities for individuals to specialize in a technology or a subset of the application.

On the other hand, there are even more advantages to small teams. These include the following:
There is less social loafing. Social loafing is the tendency for people to exert less effort when they believe there are others who will pick up the slack. Members of small teams are less prone to social loafing. Social loafing was first demonstrated by psychologist Max Ringelmann in the 1920s when he measured the pressure exerted by individuals and teams pulling on a rope. Groups of three exerted only two-and-a-half times (not three times) the average individual pressure. Groups of eight exhibited less than four times the individual average. Ringelmann’s and related studies have shown that individual effort is inversely related to team size (Stangor 2004, 220).

Constructive interaction is more likely to occur on a small team. Stephen Robbins, author of Essentials of Organizational Behavior, a best-selling textbook on organizational behavior, has concluded that teams of more than 10 to 12 people have a difficult time establishing feelings of trust, mutual accountability, and cohesiveness. Without these, constructive interaction is difficult (2005).

Less time is spent coordinating effort. Small teams spend less time coordinating the efforts of team members. This is true both in the aggregate and as a percentage of total project time. As a simple example, we all know that the effort just to plan a meeting for a large team can be overwhelming.

No one can fade into the background. With large teams, there is lower participation in group activities and discussions. Similarly, the disparity in the amount of participation among team members increases. The problems can prevent a group of individuals from jelling into a cohesive, high-performing team.

Small teams are more satisfying to their members. With a small team, one person’s contributions are more visible and meaningful. This is perhaps one reason why research has shown that participation on a large team is less satisfying to team members (Steiner 1972).

Harmful over-specialization is less likely to occur. On a large project, individuals are more likely to take on distinct roles (Shaw 1960). For example, one developer chooses to work only on the user interface. This creates wasteful hand-offs of work between team members and reduces the amount of learning that occurs when individuals are more willing and likely to work beyond specific job roles.

One interesting study of team size looked at 109 different teams. The small teams had 4 to 9 members while the large teams had 14 to 18. The researchers reached several conclusions.

Members of smaller teams participated more actively on their team; were more committed to their team; were more aware of
Chapter 10  Team Structure

the goals of the team; were better acquainted with other team members’ personalities, work roles, and communication styles; and reported higher levels of rapport. The data also show that larger teams are more conscientious in preparing meeting agendas compared to smaller teams. (Bradner, Mark, and Hertel 2003, 7)

Hmm. With a small team I can have many compelling advantages. Or I can staff a larger team and get better meeting agendas.

Small Team Productivity

Given the strength of these advantages to small teams, we would expect small teams to be more productive than large teams. Doug Putnam of QSM found exactly that after studying 491 projects with team sizes from 1 to 20 people. Since 1978 QSM has been collecting data on software productivity and estimates. The company maintains the software development industry’s most thorough metrics database, including data on application size, effort, industry, and more. As such, the QSM database is uniquely valuable for comparing different types of projects.

From the QSM database of over 7,000 projects, Putnam narrowed the data set to 491 projects completed between 2003–2005 that delivered between 35,000 and 95,000 new or modified lines of source code.¹ Project sizes were evenly distributed from 1 to 20 team members. As shown in Figure 10.1, Putnam found that the smaller the team size, the more productive each team member was. However, the difference between teams sized from 1.5 to 7 people was very small.

FIGURE 10.1
The average productivity per person on teams of various sizes. Printed with permission from QSM, Inc. All rights reserved.

¹ Lines of code is, of course, a much maligned metric and deservedly so in many cases. However, in a database of this size, I believe it is a reasonable proxy for the size of a project and can therefore be used in productivity calculations.
Putnam looked also at the total development effort that goes into projects. Not surprisingly, he found that smaller teams complete projects with less total effort. Putnam concluded that “larger teams translate into more effort and cost. The trend appears to have an exponential behavior. The most cost-effective strategy is the smallest team; however the extreme nonlinear effort increase doesn’t seem to kick in until the team size approaches nine or more people.” These results can be seen in Figure 10.2.

In most cases, however, we are not concerned with minimizing the total development effort; schedule is always a major consideration. After all, we rarely have 40 years to wait for a lone developer to finish what we need by next spring. The impact of team size on overall schedule is shown in Figure 10.3. This figure shows that a 5- to 7-person team will complete an equivalently sized project in the shortest amount of time. Smaller teams took slightly longer. Notice again the dramatic increase with teams of 9 to 11 people.

An additional study described in the Communications of the ACM compared the productivity of large and small teams. Long-time industry veteran Phillip Armour writes of this research.

Large teams (twenty-nine people) create around six times as many defects as small teams (three people) and obviously burn through a lot more money. Yet, the large team appears to produce about the same amount of output in only an average of twelve days less time. This is a truly astonishing finding, though it fits with my personal experience on projects over thirty-five years. (2006, 16)

With all of the strong reasons in favor of small teams, I don’t think I’ll be placing any orders for three pizzas any time soon.

FIGURE 10.2
Smaller teams require less total effort to deliver the same size project. Printed with permission from QSM, Inc. All rights reserved.
Favor Feature Teams

When I first began to consult for a certain California-based game studio, its teams were organized around the specific elements and objects that would exist in the video game it was developing. There was a separate team for each character. There

“There are too many disciplines on my project for us to have small teams. There are analysts, programmers, database developers, client-side programmers, middle-tier programmers, testers, test automation engineers, and more. I can’t possibly have a five- to nine-person team.”

Although a project may require work in that many disciplines, it almost certainly does not require a dedicated expert in each area. On a nine-person team with each person responsible solely for one discipline, it will be difficult or impossible to balance the workload of each team member. A team structure where some people may work only within one discipline but where others can move between two or more makes it much easier for the team to balance the workload of the different disciplines. Having at least some people work across disciplines also instills a better sense of whole-product responsibility rather than “I just do such-and-such.”

- If your team has nine or more people, try splitting into two teams after the current sprint. Work that way for at least two sprints before discussing whether it was better.
- For each team with five to nine people, consider splitting into two teams.

Things to Try Now

were weapons teams, a vehicle team, and so on. This led to problems, such as weapons too weak to kill the monsters, colors too dark to show secret passages, and obstacles that frustrated even the most patient player.

On more traditional, corporate projects, we see equivalent problems when teams organize around the layers of an application. For example, a typical early-stage mistake for the project whose architecture is shown in Figure 10.4 would be to have four teams: a rich client team, a web client team, a middle-tier team, and a database team. Creating *component teams* such as these leads to a variety of problems including

- Reduced communication across the layers
- A feeling that design by contract is sufficient
- Ending sprints without a potentially shippable product increment

If structuring teams around the layers of an architecture is the wrong approach, what’s better? Rather than organizing around components, each team on a project can ideally be responsible for end-to-end delivery of working (tested) features. A feature team working on the application shown in Figure 10.4 would, for example, work across all layers of the architecture. It might develop one feature that involves the database layer, the services tier, and the rich client user interface. In the same or next sprint, it would develop a feature going across the web client, services tier, and database tier.

There are many advantages to organizing multiteam projects into feature teams:

- **Feature teams are better able to evaluate the impact of design decisions.** At the end of a sprint, a feature team will have built end-to-end functionality, traversing all levels of the technology stack of the application. This maximizes members’ learning about the product design decisions they made (Do users like the functionality as developed?) and about technical design decisions (How well did this implementation approach work for us?).

**FIGURE 10.4**
A typical three-tier architecture.

**SEE ALSO**
The importance of delivering end-to-end functionality is discussed further in Chapter 14, “Sprints.”
Chapter 10  Team Structure

**Feature teams reduce waste created by hand-offs.** Handing work from one group or individual to another is wasteful. In the case of a component team, there is the risk that too much or too little functionality will have been developed, that the wrong functionality has been developed, that some of the functionality is no longer needed, and so on.

**It ensures that the right people are talking.** Because a feature team includes all skills needed to go from idea to running, tested feature, it ensures that the individuals with those skills communicate at least daily.

**Component teams create risk to the schedule.** The work of a component team is valuable only after it has been integrated into the product by a feature team. The effort to integrate the component team’s work must be estimated by the feature team, whether it will occur in the same sprint during which it is developed (as is best) or in a later sprint. Estimating this type of effort is difficult because it requires the feature team to estimate the integration work without knowing the quality of the component.

**It keeps the focus on delivering features.** It can be tempting for a team to fall back into its pre-Scrum habits. Organizing teams around the delivery of features, rather than around architectural elements or technologies, serves as a constant reminder of Scrum’s focus on delivering features in each sprint.

---

**OBSESSION**

“My application is too complex; I can’t possibly deliver end-to-end functionality in one sprint.”

Learning how to identify small pieces of functionality is one of the first big hurdles for a new Scrum team. I remember my first Scrum project: Initially there were times we struggled to find anything we could deliver in less than six weeks. Looking back on that system many years later, I now see many ways we could have split that work. In fact, I see enough ways to split the work now that we could have done one-day sprints if we had wanted to.

As they gain experience, team members will find many more ways to split features while still delivering end-to-end functionality within each sprint. When doing so looks impossible, it is usually because teams are not structured appropriately. Before giving up, reconsider the individuals and skills on the team.

---

**Use Component Teams Sparingly**

Although you should strongly favor the use of feature teams, there will be occasions when creating a component team is appropriate. A component team, as I’m
using the term here, is a team that develops software to be delivered to another
team on the project rather than directly to users. Examples of component teams
include a team developing an object-relational mapping layer between the appli-
cation and the database or a reusable user interface widget team.

It is important that a component team still produce high-quality, tested, po-
tentially shippable code by the end of each sprint. However, the new capabilities
created by a component team are usually meaningless on their own. Think back
for a moment to the examples I just gave. The object-relational mapping layer
developed by one of the component teams is of interest to end users only through
the context in which it is used by feature teams. But what about the team de-
veloping the reusable user interface widgets such as custom drop-down lists, data
entry grids, and so on? These are certainly of interest to end users, right? Yes, but
again only within the context of other features. An end user is not interested in a
new data entry grid until it is embedded onto a page or screen.

**Build Components Only As Feature Teams Ask for Them**

Because the work of a component team is delivered to another team, it is those
teams who usually act as the product owner for the component team. If your team
needs deliverables from my team, then you will act as the product owner to my
team. As such you will have all the responsibilities of a good product owner. At
the start of a sprint, you will need to help prioritize what I work on. At the end
of the sprint you will accept or reject it, providing feedback to me on what has
been produced.

It will be hard for you to prioritize my work and provide feedback on it if my
team is working far in advance of yours. Because of this, a component team should
not develop new capabilities until one or more feature teams is ready for them.
When a component team works far in advance of what feature teams need, they
resort to guessing at what capabilities are needed next. All too often this results in
components or frameworks that are not usable by the feature teams. All new ca-
pabilities, including those built by component teams, should be developed within
the context of externally visible functionality.

Rob was the senior developer on a component team developing an object-
relational mapping layer that would be used by many of the 15 feature teams on
the project. Rob’s team was initially tasked with choosing between developing this
technology in-house or using a commercial or open-source product. Members
made the questionable decision to build it themselves. Anxious to prove the cor-
rectness of this decision, Rob and team tried aggressively to get ahead of the needs
of the feature teams. Rather than working closely with one or more feature teams,
Rob’s component team made some big guesses about the grand design. For two
months (two sprints) members didn’t deliver anything to the feature teams. After
the third month, when they finally delivered an initial version, it did not meet the needs or expectations of the feature teams.

What Rob’s team should have done instead was work very closely with the feature teams and add new capabilities in the context of the features being delivered by the feature teams. This would have forced a much closer collaboration between the component team and the feature team, increasing the chances of delivering what was needed. Rob’s team could have, for example, delivered only the ability to write fixed-length text data to the database in the first sprint. Feature teams who received that capability would not have been able to write numeric data, dates, and so on to the database. And they would not have been able to read any data. But, the feature teams could have done one thing—write fixed-length text data—and from that could have provided feedback to Rob and his team on the usability of the component.

Perhaps the best way to ensure that a component team hears the feedback it will need to create useful functionality is to staff the component team temporarily with people from the feature teams. A developer assigned to a component team who knows he will soon be moving back to a feature team will be more likely to make sure the work of the component team will be usable.

**Deciding When a Component Team Is Appropriate**

Whenever possible, form feature teams rather than component teams. I like to start out with the assumption that all teams on a multiteam project will be feature teams. I’m willing to back away from that assumption, but I only want to do so in the face of evidence that forming one or more component teams will be in the best interest of the product. I suggest considering a component team only when most of the following statements are true:

- **The component team will build something that will be used by multiple feature teams.** If a component will be used by only one feature team, have that feature team build it. This ensures that the new capability is built within the context of that team’s needs and expectations, which makes the implementation more likely to be used. Even when a component team will build something useful to multiple teams, a better strategy is often to have one feature team build the functionality it needs and then have subsequent teams refactor and generalize the functionality as their needs arise.

- **Using a component team will reduce the sharing of specialists.** On some multiteam projects, some highly specialized disciplines are shared across many teams. Although some sharing of specialists is usually necessary, too much of it can be detrimental as the specialist’s time becomes too fragmented. You may want to consider creating a component team if doing...
Favor Feature Teams

so will make more manageable the extent to which specialists are shared across many teams.

- **The risk of multiple approaches outweighs the disadvantages of a component team.** If we choose to build a shared component or service by having multiple feature teams contribute to the effort, there are two related risks to be aware of. First is the risk that each feature team implements a different solution to the same problem. Second is the risk that the feature teams each build on top of what prior feature teams have done but do so without a cohesive vision. These risks could be great or small, depending on what shared functionality is being built. When the risk of multiple approaches is high, a component team is a valid option.

- **It will get people talking who might not talk otherwise.** People tend to talk more with those on their team than those outside their team. This is true even on a Scrum project. In fact, it may be especially true on a Scrum project because team members on Scrum projects come to identify so strongly with their teams. You can use this to your advantage by creating teams from people who need to work together but who might not naturally talk to each other. If past experience shows that a project’s artificial intelligence programmers do not talk often enough, this can help justify the short-term use of a component team, as long as there are other reasons for doing so.

- **You can see an end to the need for the component team.** A component team should not linger around forever, like my in-laws after the holidays. The team should develop the functionality it has been pulled together to create and then disband as soon as possible. When first forming a component team, it is not necessary to know when it will disband; however, you should have some idea of either how long it will exist or what will be delivered by the time the team has fulfilled its purpose. Because a component team is a deviation from the ideal of having all feature teams, you should be reluctant to create a component team that looks as though it might exist forever.

While acknowledging the occasional benefits of using a component team, I want to stress again that the vast majority of teams on a large project should be feature teams. Wes Williams and Mike Stout have described what happened at Sabre Airline Solutions when beginning with component teams.

Stories weren’t complete from a user perspective. Teams were working on different features at different times with different acceptance criteria. There was a lot of rework coming back into the system. Teams were blaming each other for incomplete functionality, failing builds, test, etc. In hindsight...the teams
should have been structured along functional or feature lines.
(2008, 359)

**Who Makes These Decisions?**

Ideally, the team makes decisions about how it is structured. If the team is to be trusted with solving the problem of how to build the product, it seems appropriate to trust it with the decision about how to structure itself to do so. However, though team members are accustomed to making technical decisions, they usually do not have a lot of experience making team organization decisions. So, initially the team may not be in the best position to design its own structure.

I’ve introduced Scrum to hundreds of teams. One of the things I’ve noticed is how frequently someone’s initial exposure to Scrum results in an opinion like, “Scrum sounds wonderful for our company, and it will be great for all the other groups but not mine.” Architects add, “After we do the up-front architecture, I can really see how this will help the programmers and testers.” User experience designers say, “After we’ve done the up-front usability research, I can really see how this will work for the architects, programmers, and testers.” Testers take the initial view, “It will be wonderful to have everyone working so closely together and then handing off to us for a big round of integration testing.”

If we ask team members with these common initial mindsets to design the structure of their multiteam project, it shouldn’t surprise us when they come back with plans for an architecture team, a programming team, a user experience team, and a test team. Of course I’m generalizing, but the tendency to think this way is so prevalent that it will be tempting to organize that way as well.

Initially, then, it is likely that functional managers, project managers, Scrum-Masters, or those driving the transition to Scrum will make the decisions about how to organize the teams. These decision makers should solicit nonbinding input from their teams, especially from team members with past experience with Scrum or other agile methodologies.

**What’s Right Today May Be Wrong Tomorrow**

An important thing to remember when selecting an appropriate team structure is that no team structure is forever. If the current team structure is impeding a team’s or project’s ability to use Scrum, that issue should be raised during an end-of-sprint retrospective. You don’t want to continually change team structures, as team members need time to jell, but if the current structure is clearly wrong, change it.

As team members gain more experience with Scrum, it will be appropriate for them to become more involved in team structure decisions, including which teams are needed, whether each is a feature or component team, and who should be on each team.
The ability for a team to self-organize around the goals it has been given is fundamental to all agile methodologies, including Scrum. In fact, the Agile Manifesto includes self-organizing teams as a key principle, saying that “the best architectures, requirements, and designs emerge from self-organizing teams” (Beck et al. 2007). As part of deciding how best to achieve the goal given them, some teams will decide that all key technical decisions will be made by one person on the team. Other teams will decide to split the responsibility for technical decisions along technical boundaries: Our database expert makes database decisions, and our most experienced C# programmer makes C# decisions. Still other teams may decide that whoever is working on the feature makes the decision but has the responsibility of sharing the results of the decision with the team.

There are two key points here: First, not every team will choose to organize themselves the same way, and that’s OK. Second, making use of the collective wisdom of the team will generally lead to a better way of organizing around the work than will relying solely on the wisdom of one personnel manager. However, the benefit of allowing a team to self-organize isn’t that the team finds some optimal organization for their work that a manager may have missed. Rather, it is that by allowing the team to self-organize, they are encouraged to fully own the problem.

A common criticism of self-organizing teams is, “We cannot just put eight random individuals together, tell them to self-organize, and expect anything good to result.” Well, I don’t know if that’s true, but when we are putting together a two-pizza Scrum team, we are definitely not doing so with eight randomly selected individuals. In fact, those in the organization responsible for initiating a Scrum project should expend a lot of effort in selecting the individuals who will comprise the team.

In the original paper describing Scrum, Takeuchi and Nonaka identified “subtle control” as one of its six principles. They list staffing decisions as a key management responsibility.

Selecting the right people for the project team while monitoring shifts in group dynamics and adding or dropping members when necessary [is a key management responsibility]. “We would add an older and more conservative member to the team should the balance shift too much toward radicalism,” said a Honda engineer.
Getting the Right People on the Team

If you are a personnel manager or otherwise influence team composition in your organization, some of the factors to consider are the following:

- **Include all needed disciplines.** As a cross-functional team, it is important that all skills necessary to go from idea to implemented feature be represented on the team. Initially this may mean that team size is slightly larger than desired. But, over time, individuals on a Scrum team will learn some of the skills possessed by their coworkers. This is a natural result of being on a Scrum team. As some team members develop broader skills, other individuals can be moved onto other teams.

- **Balance technical skill levels.** Subject to considerations of team size, you should strive to balance skill levels on the team. If a team has three senior programmers and no less-experienced programmers, the senior programmers will need to code some low-criticality features that they could find boring. Not only might a junior programmer have found such features enjoyable to work on, that programmer would also benefit from learning through association with the senior programmers.

- **Balance domain knowledge.** Just as we strive to balance technical skills, we should strive for a balance between those with deep knowledge of the domain in which we are working or the problem we are attempting to solve. This is not to say that if we have the opportunity to assemble a team entirely of domain experts we shouldn’t take it. Rather, we should consider the long-term goals of our organization. One of those goals is likely the build up of domain knowledge throughout the organization. You’ll have a hard time achieving that if you put all of the domain experts on one team.

- **Seek diversity.** Diversity can mean many different things—gender, race, and culture being just three among them. Perhaps equally important can be how individuals think about problems, how they make decisions, how much information they need before making a decision, and so on. Homogeneous teams reach consensus more quickly than do heterogeneous teams, but they do so by failing to consider all options (Mello and Ruckes 2006).

- **Consider persistence.** It takes time for team members to learn to work well together. Strive, therefore, to keep team members together who have worked well together in the past. When forming a new team, consider
how long members will be able to work together before some or all are dispersed to other commitments.

“We can’t self-organize because we have a dominating former technical lead who makes all decisions before we even have a chance to discuss the issue.”

If possible, take the dominating personality aside and inform her of the issue. Let her know that even in situations where she may know the “right” thing to do, she should sometimes refrain from voicing her opinion before others have a chance to express their thoughts. Ask her if she thinks the team would make the right decision if she were to present her thoughts as an opinion rather than as an unchallengeable decision. Enlist her assistance as a mentor to the others—her job should be not just making sure the right decisions are made but that team members grow such that they will make the right decisions on their next projects, where she may not be there for them.

“My team won’t self-organize; team members are too passive and look to me to lead.”

If they look to you, look back right at them. If you are the team’s Scrum-Master, make sure they know that your job is to support them, not to make decisions for them. If you are a team member, you do not need to subjugate your opinions and keep quiet all the time. However, you should look for ways to engage others by not making the decision in all cases. For example, try asking questions of others before giving your opinion.

“The team is too junior; members don’t have enough experience to self-organize.”

If they have enough experience to build a software product, they probably have enough experience to figure out how to organize themselves. If not, provide them with training or coaching. Often, this objection really masks the objection of, “I don’t trust the team to self-organize in the way I want them to.” Too bad. Exert subtle control over the team in who you put together to form the team and the goal you give that team, not in how it does its day-to-day work.

Put People on One Project

Individuals assigned to work on multiple projects inevitably get less done. Multitasking—attempting to work on two projects or two things at once—is
Chapter 10  Team Structure

one of the biggest drains on project team performance. Yet it has unfortunately become one of the busy manager’s most frequently used tools. The reason for this, I believe, is that multitasking creates the illusion of progress and gives the manager the feeling that a problem has been solved. Really, though, in many cases the problem has been made worse.

Consider the case of Jon, a director of database engineering who managed a staff of database administrators (DBAs) who were woefully outnumbered by the programmers, testers, and other types of developers in his company. Jon was faced with allocating himself and his staff of five across more projects than they could handle. His solution was to create a spreadsheet like the one shown in Figure 10.5. Jon’s spreadsheet allowed him to allocate DBAs across the various projects, which he did down to the 5% level. Five percent of an 8-hour day is 24 minutes. Through this spreadsheet Jon was telling Bill he could spend 24 minutes each on the Napa and PMT projects, Ahmed could spend the same on PMT and Spinwheel, and so on.

![Figure 10.5](image)

A portion of Jon’s project staffing spreadsheet.

Did Jon really think that Bill would stop working on the Napa project after 24 minutes each day? Of course not. But he probably did think that Bill had enough control over his schedule that he could be close to \( 24 \times 5 = 120 \) minutes in a week. What Jon was really doing in this situation was taking a problem (the correct allocation of resources) that he couldn’t solve and pushing it down to the members of his team. What Jon should have done instead was push this problem up to his own manager.

Pushing problems toward the team is often a wonderful strategy. In fact, delegating problems to the team is at the heart of Scrum. However, when a problem is pushed toward the team, the team needs to be given the authority to solve the problem. In the case of Jon and his DBAs, it was obvious that one solution to
consider was doing fewer concurrent projects. Without being empowered to enact that solution, they were put into an impossible-to-solve situation.

And they didn’t solve it any better than Jon did. They invoked the age-old policy of “work on the project of whoever is screaming the loudest.”

**Time on Task Decreases with Too Many Tasks**

Kim Clark and Steven Wheelwright studied the impact of multitasking on productivity. Their findings, shown in Figure 10.6, indicate that the total amount of time on task goes up when a person has two tasks to work on. After that, however, Clark and Wheelwright found that time on task decreased. In fact, with three tasks the amount of time on task decreased so much it was less than when an individual had only one task to work on (1992, 242).

If you have only one task to work on it is almost a certainty that you will occasionally be unable to work on that task. You will become blocked by waiting for someone to return a phone call, answer an e-mail, approve the design, or so on. And so it makes sense that the Clark and Wheelwright study shows that a person with two tasks to work on spent more time on task than did someone with only one task. However, consider that Clark and Wheelwright did this research in the early 1990s.

What’s changed since then? For starters how about e-mail, instant messaging, the proliferation of mobile telephones, and any number of ways in which we communicate? My theory is that the bars in Figure 10.6 need to be shifted one space to the left to reflect today’s faster pace. I remember clearly the job I had back in 1992 when Clark and Wheelwright published their results. I remember times back then when I was at my desk and thought, “I’m caught up; I have nothing to do right now.” Of course, I haven’t thought that since 1992.

The pace of the world has accelerated dramatically. Just being a good corporate citizen takes more time now than it did in 1992. There’s more to read, more to...
process, and more for each person to do. Merely being an employee should count today as a first task for each of us. The first project we are on counts as a second, and we are then already optimally productive. Any further projects we are assigned just make us less productive.

One of the main reasons that multitasking is so horrible is the task-switching cost involved. There is tremendous overhead in getting started on one task, switching to another, and then switching back to the first. The more tasks or projects we are involved in, the more likely we are to be interrupted while working on them. One study of members of a software development team found that team members are interrupted every 11 minutes (Gonzales and Mark 2004). If you’re reading this chapter at the office, it is likely that you were interrupted at least once while reading.

THING TO TRY NOW

If you are a manager, make a list of your direct reports and the projects each is on. If anyone is on more than two projects, immediately find a way to change that. If you’ve already achieved this, see if you can reduce someone’s allocation from two projects to one. Assess the situation after two sprints.

When Multitasking Is OK

All of this is not to say that we should never allow multitasking on our projects. It is sometimes helpful. The key is to remember that a person who is multitasking and shared across multiple projects is likely to get less total work done than if she had been dedicated fully to just one of those projects.

Let’s again consider Jon and his DBAs. Suppose each DBA could complete “20 database tasks” per day assuming that all database tasks are the same size. A DBA fortunate enough to work on only 1 project would achieve this level of performance. However, a DBA on 2 projects might complete only 16 database tasks per day. And a DBA on 3 projects might complete only 14 database tasks per day.

Although these reduced levels of productivity may look quite bad, they may not be. Suppose 1 of our DBAs is assigned to 2 projects and is to split her time equally between them. She will be able to complete 8 database tasks on each project. This may be the optimal use of her time if neither of the projects needs 20 database tasks done in a day. If neither project needs more than 8 database tasks a day from her, then she is better split between both projects than dedicated entirely to 1. From this we can extract the following guidelines:

- In general, and for the majority of a project’s team members, multitasking is to be avoided.
- Multitasking may be acceptable if a person cannot be fully or nearly fully utilized on a single project. If we look back to Figure 10.5 and Jon’s DBAs, we see that the Connect project was allocated three people...
with a total allocation greater than 100%. A better solution would likely have been to allocate a single person but for 100% of his time.

- Rather than have everyone multitask a little, it is better to have a few people multitask a lot. Figure 10.6 illustrates how the largest drop in time on task occurs after a person takes on the first task too many. In Jon’s case, a better solution would have been to do anything possible to have two or three of his DBAs not have to multitask, even if that meant the others had to multitask even more.

The Corporate Form of Multitasking

Individuals feel compelled to multitask because the organizations in which we work attempt to multitask as well. The corporate form of multitasking is pursuing too many concurrent projects. When an organization takes on too many projects, people become shared across multiple projects, which leads to individual multitasking. The detrimental effect of multitasking then causes those projects to take longer, which leads to more multitasking near the end of the project when “we need to get started” on the next project.

An eight-year study of projects at a dozen companies and published in Harvard Business Review concluded that “projects get done faster if the organization takes on fewer at a time” (Adler et al. 1996). Corporate multitasking—attempting to make progress on too many concurrent projects—is what created the situation that Jon found himself in earlier in this chapter when he resorted to allocating his people to the 5% level.

Mary and Tom Poppendieck urge organizations to limit work to capacity. An organization that has more projects running concurrently than can be adequately staffed is attempting to work beyond its capacity. As they write, “If you expect teams to meet aggressive deadlines, you must limit work to capacity (2006, 134, emphasis is theirs).

Stopping the Treadmill

One of the happiest days of my life as a consultant was when I explained the impact of personal and corporate multitasking to the general manager of a large division of a big company. I could tell the message resonated with her. She asked me to follow her as she rose from her desk. We walked to a conference room near her office. She pointed toward a huge number of sticky notes stuck to the widest wall in the conference room and said, “We just made our plan for next year. There it is. Do you think we’re doing too much?”

Her division had well over 100 developers but the wall was full. We talked about the plan, the number of concurrent projects, and the ripple effect that would occur if one project was substantially late. She knew they were planning to
do too much, and I confirmed this for her. She convened a meeting for the next
day of the vice presidents and directors who had made the plan and instructed
them to start taking projects off the board. A look of relief (and surprise) went
across the faces of everyone present. They had each known that the plan they had
created the week before was overly ambitious and would not happen. However,
no one had been willing to say so.

I checked back with this general manager a year later and was delighted—but
not surprised—to hear that her division had just completed its most successful
year ever. Part of that was attributable to the adoption of Scrum and the improve-
ments it brought across her department. But an equal part of the success was at-
tributable to the focus that was brought to each project by having fewer projects
in progress at one time.

As this anecdote shows, often the best way to stop multitasking is to stop cold
turkey. However, the reason I was so impressed with this general manager is that
she is one of the few I have seen with the courage to do that. If you can’t stop
immediately, or if you’re not in a position within the organization to make such a
far-reaching decision, there are other things you may want to try.

**Don’t start a new project until it can be fully staffed.** Avoid the temptation to start
a new project with just a few analysts and maybe one programmer. Try to get
everyone to agree that new projects will be started only when they can be staffed
with all disciplines represented. This isn’t to say you need to wait to start a large
project until all 50 developers are available. Starting a new project only when at
least one full team can be fully and appropriately staffed will help adjust the rate
at which new projects are started to closer to the rate at which they can be de-
veloped.

**Include ramp-up and wind-down time in enterprise plans.** If, like the general man-
ger in this section’s story, you put together a big, annual plan, be sure to include
the time necessary to start and stop the various projects. All too often a team
provides an estimate of six months, and six months are reserved on an enterprise
calendar. However, even on a Scrum project (especially from a new Scrum team),
there may be a month or two of wind-down. During this time at least a subset of
the team may be needed for high-priority bug fixes or to implement great, new
ideas that were discovered only upon release. Failing to plan for some of this will
cause unexpected periods of overlapping projects.

**Institute simple rules.** Gaining agreement on simple rules can help lead to the
right organizational behavior. A simple rule such as “No one can be assigned to
more than two projects,” can work wonders. Johannes Brodwall, chief scientist
with Steria in Norway, suggests one simple rule.
Everyone on the team must be at least 60% allocated to the team. Sixty percent seems to be a magical number, which says to people, “This is the most important thing.” With 60%, when one task suffers, it is usually one of those 10% or 20% tasks. So this structure guides people to be more dedicated to their primary team.

**Go slow but go.** I can totally respect the leap of faith required to believe that doing fewer concurrent projects will lead to more projects being completed. Even if they believe that completing projects more quickly will ultimately lead to increased productivity, people will be uncomfortable postponing or canceling large-scale projects. So, start small: Remove one project from the first quarter plan and see how it goes.

**Guidelines for Good Team Structure**

This section presents a set of guidelines to consider in designing an appropriate team structure. Each guideline is presented in the form of a question to be asked of a current or proposed team. The questions are intended to be asked iteratively. Ask each question of a current or proposed team, changing the structure as appropriate based on the answer. As the structure changes, reask the questions until you can answer “yes” to each.

**Does the structure accentuate the strengths, shore up the weaknesses, and support the motivations of the team members?** People don’t enjoy being on a team where they are not able to make use of their strengths or are constantly required to do things they are bad at. Good team members are willing to do whatever is necessary for the success of the project, but that doesn’t relieve us from the goal of trying to find a team structure that accentuates the strengths of as many team members as possible.

**Does the structure minimize the number of people required to be on two teams (and avoid having anyone on three)?** A well-conceived team structure for an organization that is not attempting to do too many concurrent projects will reduce multitasking to a tolerable level. If the organization is not attempting too many concurrent projects, yet more than 10–20% of all team members belong to more than one team, consider an alternative team design or deferring some projects.

**Does the structure maximize the amount of time that teams will remain together?**

If other factors are equal, you should favor a design that allows team membership to persist over a longer period. It takes time for individuals to learn to work well
together. Amortize the cost of that learning over a longer period by trying to leave teams together as long as possible, ideally even finding a team structure that can outlast the current project.

**Are component teams used only in limited and easily justifiable cases?** Most teams should be created around the end-to-end delivery of working features. In some cases, it is acceptable to have a component team developing reusable user interface components, providing access to a database, or similar functionality. But these should be exceptions.

**Will you be able to feed most teams with two pizzas?** Given the compelling productivity and quality advantages of small teams, the majority of teams in a good design should have between five to nine members.

**Does the structure minimize the number of communication paths between teams?** A poor team structure design will result in a seemingly infinite number of communication paths between teams. Teams will find themselves unable to complete any work without coordinating first with too many other teams. Some interteam coordination will always be required. But, if a team that wants to add a new field on a form is required to coordinate that effort with three other teams, as I’ve seen, then the communication overhead is too high.

**Does the structure encourage teams to communicate who wouldn’t otherwise do so?** Some teams will just naturally communicate with each other. An effective team design encourages communication among teams or individuals who should communicate but may not do so on their own accord. In fact, one valid reason to put someone on two teams is that doing so will increase the communication between those teams. If lack of communication between two teams is a concern, splitting a person’s time between those two teams is easily justified.

**Does the design support a clear understanding of accountability?** A well-designed team structure will reinforce the concept of a shared, all-teams accountability for the overall success of the project while providing each team with clear indicators of their unique accountabilities.

**Did team members have input into the design of the team?** During the early stages of your transition to Scrum, this may not be possible. Individuals may not yet have enough experience delivering working, tested, ready-to-use products by the end of each sprint. Similarly, some individuals may be initially too resistant to Scrum to contribute to team structure discussions in constructive ways. In these cases, it is acceptable for managers outside the team to design an initial team structure.
While doing so, however, they should remember that this is a responsibility that will eventually need to be turned over to the team as a whole.

Onward

In this chapter we’ve looked at why Scrum teams should be kept small and used the analogy of being able to feed each team with two pizzas. To further enhance a team’s ability to rapidly, correctly, and efficiently develop software products, we also considered whether teams should be structured around features or components. We concluded that in structuring multiple teams, we should seek to favor feature teams and try to avoid the use of component teams, while acknowledging they will occasionally be appropriate.

Next we dispensed with the myth that a self-organizing team is a random collection of individuals. As with any team, team members should be chosen with effort and care. We also looked in detail at the need to structure teams in such a way as to minimize the need for individuals to belong to two or more teams. Finally, we concluded with nine guidelines for structuring teams.

In the next chapter we turn our attention to the subject of teamwork. We look specifically at what the members of a single, two-pizza team can do to work well together during a sprint.

Additional Reading

It is impossible to say enough good things about this book. I remember the day in 1989 when my CEO told me, “After reading *Peopleware* this weekend, I am going to completely change our development group.” She did, and the group excelled because of it. This book is full of advice on helping teams achieve their fullest potential.

This book precedes the agile movement but still contains some of the best advice on various team structures. Two chapters include a summary of various team structure options, how to choose among them, and case studies of how six teams chose to organize.

The premise of this book is that a leader’s job is to design and support teams that can manage themselves. It includes an excellent chapter (“Enabling Structure”) on how to structure teams.
